

## COMPLEXES AND CHELATES

"The chelate is a product that can provide the nutrient to the plant faster and much better than the conventional fertilizer because it does not suffer 'reaction' with the products of the spray grout, being readily available at the time the plant needs it, even if sprayed days ago, because it meets exactly at the 'time of the opening of the physiological window of the plant', not to mention that a chelate, depending on the nutrient, provides 2 to 10 times more amount than the one provided without being complexed or chelated!"

The use of complexing and chelating agents extends to various fields, among which are food, home and personal hygiene, medicine, among others, given their functionalities such as, for example, sequestering cations in detergents, aiding in cleaning.
